

Researchers design superhydrophobic 'nanoflower' for biomedical applications

Plant leaves have a natural superpower—they're designed with water repelling characteristics. Called a superhydrophobic surface, this trait allows leaves to cleanse themselves from dust particles. Inspired by such natural designs, a team of researchers at Texas A&M University has developed an innovative way to control the hydrophobicity of a surface to benefit to the biomedical field. applications in the biomedical field including biosensing, lab-on-a-chip, blood-repellent, anti-fouling and self-cleaning applications. Superhydrophobic materials are used extensively for self-cleaning characteristic of devices. However, current materials require alteration to the chemistry or topography of the surface to work. This limits the use of superhydrophobic materials. "Designing hydrophobic surfaces and controlling the wetting behavior has long been of great interest, as it plays crucial role in accomplishing self-cleaning ability," Gaharwar said. "However, there are limited biocompatible approach to control the wetting behavior of the surface as desired in several biomedical and biotechnological applications." The Texas A&M design adopts a 'nanoflower-like' assembly of two-dimensional (2-D) [atomic layers](#) to protect the surface from wetting. The team recently released a study published in *Chemical Communications*. 2-D nanomaterials are an ultrathin class of nanomaterials and have received considerable attention in research. Gaharwar's lab used 2-D molybdenum disulfide (MoS₂), a new class of 2-D nanomaterials that has shown [enormous potential](#) in nanoelectronics, optical sensors, renewable energy sources, catalysis and lubrication, but has not been investigated for biomedical applications. This innovative approach demonstrates applications of this unique

class of materials to the biomedical industry.

This innovative technique opens many doors for expanded applications in several scientific and technological areas. The superhydrophobic coating can be easily applied over various substrates such as glass, tissue paper, rubber or silica using the solvent evaporation method. These superhydrophobic coatings have wide-spread applications, not only in developing self-cleaning surfaces in nanoelectronics devices, but also for [biomedical applications](#). Specifically, the study demonstrated that blood and cell culture media containing proteins do not adhere to the [surface](#), which is very promising. In addition, the team is currently exploring the potential applications of controlled hydrophobicity in stem cell fate.
